

Abstract

A technical object of the present invention is to provide a three-dimensional image displaying system having an ability to provide an observer with a three-dimensional image that is easy to see. In a three-dimensional image displaying system (1) of the present invention, a display device (3) sequentially executes a display process for a piece of data outputted from an image generating device (2) so as to emit a light which is a plurality of lights multiplexed over a time axis, wherein each light represents an object. A focal length changing device (4) gives a sense of three-dimensionality, in other words, a sense of distance to each object included in the light so as to generate a three-dimensional image light having an ability to enter a vision in three-dimensional manner. A reflection component (6) reflects the multiplexed light in a direction of the observer (V) so as to provide the observer with a three-dimensional image in which the object is synthesized. Therefore, not only an image of the object which is currently displayed is visually recognized by the observer, but a residual image of other objects remaining in a retina of the observer (V) is also recognized by the observer (V).
